components. SBP, PWV, smoking or central adiposity was directly related to Component 1 and inversely to component 4, whose pattern was higher AA, eicosapentaenoic (EPA) and DHA and lower oleic, palmitic (PA) and linoleic (LA) levels. Component 4 was associated with a decreased risk of mortality (HR 0.49 (0.39, 0.62) independent of PWV. Component 1, associated with increased mortality (HR = 1.13, 1.01-1.27), included people with higher levels of the saturated FAs (myristic and PA) but lower levels of polyunsaturated FAs (LA, dihomo-gamma-linolenic (DGLA) & AA).

Conclusion: Patterns of serum fatty acids, partially reflecting diet, are associated with mortality, perhaps by modulating large vessel vascular function.

Background: few data are available on cardiovascular (CV) involvement in young DM1 subjects with disease onset in pediatric age.

Aim: to assess preclinical CV changes in young patients with early onset DM1.

Methods: Thirty DM1 normotensive subjects (age =19.4±3.2 years, BMI=22.1±2.7 kg/m², disease duration=10.7±5.4 years, HbA1c=7.8±1.4%) without macro- and microvascular complications, and 14 controls (C) of comparable age and BMI. Common carotid artery (CCA) IMT, local stiffness (β and Ep) and wave speed (WS) were obtained by echo-tracking (Aloka Alpha10). Aortic stiffness was assessed by carotid-femoral pulse wave velocity (PWV). Myocardial tissue velocities, LV geometry and function were evaluated by echocardiography.

Results: DM1 had, compared to C, higher (p<0.05) diastolic BP (DBP: 68±7 vs 62±4 mmHg), interventricular septum thickness (IVS) (0.76±0.11 vs 0.65±0.10 cm) and LV relative wall thickness (RWT: 0.31±0.4 vs 0.28±0.03). No differences between groups were found for pulse pressure, LV mass index, midwall shortening, transmitral E/A, myocardial velocities, CCA IMT and stiffness, WS and PWV. In the entire population, DBP increased with age, BMI, WS and PWV (r from 0.33 to 0.38, p < 0.05), and IVS increased with SBP and BMI (r=0.35 and 0.49, p<0.05). Independent predictors of DBP were WS and DM1 (R²=0.23, p<0.005), whereas predictors of IVS were sex, BMI and DM1 (R²=0.53, p<0.0001). RWT was independently related to DM1 (R²=0.12, p<0.05).

Conclusions: well controlled young DM1 subjects show mildly elevated DBP and a trend towards LV concentric remodelling. Whether arterial stiffness is mechanism or result of increased DBP remains to be established.

Background: Non-alcoholic fatty liver disease (NAFLD) is associated with metabolic syndrome, a marker of increased cardiovascular risk. Aortic stiffness, flow-mediated dilation (FMD) and intima-media thickness (IMT) are markers of cardiovascular disease and independent predictors of the corresponding risk. We investigated whether the presence and the histological activity of NAFLD are associated with arterial function and early vascular changes.

Methods: A total of 51 subjects participated in this study, 23 patients (mean age 55±14 yrs, 48% males) with biopsy evidence of NAFLD but without cirrhosis, and 28 control subjects adjusted for age, gender and other cardiovascular risk factors. Carotid-femoral pulse wave velocity (PWV) was measured as index of aortic stiffness. FMD of the brachial artery, an index of endothelial function, and mean IMT of common carotid arteries, a marker of subclinical atherosclerosis, were measured using B-mode ultrasound imaging.

Results: NAFLD subjects had significantly higher PWV (8.2±1.3 m/sec vs. 6.9±1.3 m/sec, P=0.001), and higher carotid IMT (0.78±0.17 mm vs. 0.67±0.13 mm, P=0.01) compared to controls. NAFLD subjects had significantly reduced FMD (1.92±2.11% vs. 4.8±2.43%, P<0.001) compared to controls. Multivariable regression analysis, showed that histological activity was associated independently with FMD (β=-0.388, P=0.037). Leptin was an independent determinant of PWV (β=0.384, P=0.003). FMD was independently associated with both leptin (β=-0.294, P=0.035) and adiponectin (β=0.366, P=0.008).

Conclusions: Patients have higher PWV and IMT and lower FMD compared to controls, indicating both functional and structural impairment in large arteries. The histological activity of NAFLD and levels of adipokines predict the degree of arterial impairment.

Background: Non-alcoholic fatty liver disease (NAFLD) is a component of metabolic syndrome, which is a marker of increased cardiovascular risk. Flow-mediated dilation (FMD) is an independent prognostic factor of cardiovascular risk. Adiponectin is an adipose - tissue hormone and has vasculoprotective effects. We investigated whether NAFLD is associated with impaired arterial function and the role of adiponectin in this relation.

Methods: We studied 19 hypertensive patients (age 57±12 years, 9 males) with biopsy evidence of NAFLD, and 14 hypertensive control subjects adjusted for classical risk factors. The changes in the diameter of the brachial artery were measured in response to reactive hyperemia and also in response to nitroglycerin. Adiponectin levels were measured by ELISA kit.

Results: NAFLD subjects had significantly reduced flow-mediated vasodilation (2.07±2.26% vs 5.57± 2.8%, p<0.01), while nitroglycerin-mediated vasodilation did not differ among the two groups. Systolic, diastolic and pulse pressure were not different among the two groups. NAFLD subjects had significantly reduced levels of adiponectin (8.98±6.32 µg/ml vs 17.08±8.57 µg/ml, p<0.01) compared to controls. Interestingly enough, adiponectin levels were associated with flow-mediated dilation (r=0.403, p<0.05).

Conclusion: Although the initiating events that trigger the impaired arterial function in NAFLD patients cannot be ascertained, the role of adipocytokines may identify a potential basis.

THE PRESENCE OF CIRRHOSIS AMELIORATES THE ARTERIAL STIFFNESS IN PATIENTS WITH NON-ALCOHOLIC STEATOHEPATITIS

Background: Non-alcoholic steatohepatitis (NASH) is linked with metabolic syndrome and is associated with increased cardiovascular risk. NASH is characterized by steatosis, inflammation, and fibrosis and may progress to cirrhosis. Aortic stiffness and wave reflections are independent markers and predictors of cardiovascular risk. We investigated the arterial stiffness in NASH patients with or without cirrhosis.

Methods: The study population consisted of 34 subjects (mean age: 62.2 ± 10.2 yrs, 9M/25F). In particular, 19 had bioptical evidence of NASH, cirrhosis was present in 7 of them and 12 NASH patients had no bioptical or biochemical evidence of cirrhosis. 14 subjects without liver disease were recruited in this study. The three groups did not differ in classical risk factors. Carotid-femoral pulse wave velocity (PWV) was measured as index of aortic stiffness. Augmentation index (Alx) of the central (aortic) pressure waveform was measured as an index of wave reflections.

Results: PWV was significantly increased in NASH patients without cirrhosis compared to controls (9.3 ± 1.6 vs 7.7 ± 1.3 m/s, p<0.05), but cirrhotic patients had significantly reduced PWV compared to NASH patients without cirrhosis (7.2 ± 1.2 vs 9.3 ± 1.6 m/s, p<0.05), while Alx did not differ.

Conclusions: The transition of NASH to cirrhosis is followed by the paradoxical improvement of the stiffen arteries, which may be explained
