Physical exercise augmentation index

ABSTRACT

Purpose: To compare augmentation index (AIx) between one Moderate-intensity continuous physical exercise (MICPE) and one High-intensity interval physical exercise (HIIPE) session in normal/high normal blood pressure (BP) (120–140 for systolic and 80–90 mmHg for diastolic). Additionally, to compare two AIx methods (SphygmoCor* and Arteriograph*) [1].

Methods: Exercise intensity and energy expenditure (equalizing) were according to the cardiopulmonary stress test. Individuals were randomized to exercise sessions, performed as cross-over. AIx were analyzed at baseline, immediately after and 24hours after MICPE and HIIPE session and compared among all times. Δ AIxHIIPE (AIxHIIPE - AIxBaseline) and Δ AIxMICPE were calculated. Correlation and agreement analysis was performed between AIx methods.

Results: Individuals (n = 23; 78% women; 48 ± 1 years; systolic/diastolicBP = $125 \pm 2/84 \pm 1 \text{ mmHg}$) had lower AIxSphygmoCor^{*} at MICPE compared to baseline and to 24 hours MICPE ($27.2 \pm 2.2 \text{ vs } 32.8 \pm 1 \text{ and } 31.0 \pm 2.5\%$; p < 0.01). AIxSphygmoCor^{*} was lower in HIIPE than other times ($23.2 \pm 2.4 \text{ vs baseline } 32.8 \pm 1.9 p < 0.01$; vs MICPE 27.2 ± 2.2 ; p = 0.039; vs 24 hours MICPE $31.0 \pm 2.5\%$; p < 0.01 and vs 24 hours HIIPE $32.2 \pm 2.0\%$; p < 0.01). AIxArteriograph^{*} was lower in HIIPE ($16.0 \pm 3.7\%$) than baseline ($28.9 \pm 3.4\%$; p = 0.001), 24 hours MICPE ($25.7 \pm 4.0\%$; p = 0.008) and 24 hours HIIPE ($29.5 \pm 3.9\%$; p = 0.005). Δ AIxHIIPE was greater than Δ AIxMICPE (-9.37 vs -5.15; p = 0.028). AIxArteriograph^{*} showed a positive correlation with AIxSphygmoCor^{*} (r = 0.793; p < 0.01) and showed agreement.

Conclusion: Regardless of intensity, one exercise session improves AIx. The effect seems to be greater after HIIPE than MICPE.
